

Tooth Restorations

The incidence of tooth decay has considerably decreased in the past decades due to the use of fluorides and an increase in patient's oral health awareness. Nevertheless, teeth still suffer from decay, infection, and breakage and oftentimes need some dental restorations to get them back to health. Techniques and dental technologies have greatly improved enabling many new and advanced treatment options able to restore a tooth back to its natural shape, appearance and function.

There are many reasons why a patient may require restorative dentistry such as repairing damaged and decayed teeth, filling improving or correcting an incongruous bite, to prevent the loss of a tooth, to relieve dental pains, to replace lost or missing teeth, to restore normal chewing and eating, and to replace old or unattractive dental treatments. Also, cosmetic reasons such as enhancing your smile and covering up unattractive spaces between your teeth have become more common practice these days.
